(54) Title: DRUG DELIVERY FROM EMBOLIC AGENTS

(57) Abstract: A pharmaceutical composition for uterine fibroid embolisation comprises a polymer and, associated with the polymer in a releasable form, a COX inhibitor, e.g. a non-steroidal anti inflammatory drug, such as ibuprofen. The polymer is preferably in particulate form, such as in the form of microspheres. A suitable polymer is a crosslinked polyvinyl alcohol polymer formed by the copolymerisation of PVA macromer with other ethylenically unsaturated monomers. The composition provides a synergistic treatment for the symptoms of uterine fibroids, leading to size regression as well as pain relief.

1

DRUG DELIVERY FROM EMBOLIC AGENTS

The present invention relates to compositions which embolise uterine fibroids and deliver drugs at the site of embolisation. The drugs are non-steroidal anti-inflammatory drugs (NSAD's) and have cyclooxygenase (COX) inhibitory properties which will reduce inflammation caused by embolisation.

Embolisation therapy involves the introduction of an agent into the vasculature in order to bring about the deliberate blockage of a particular vessel. This type of therapy is particularly useful for blocking abnormal connections between arteries and veins (such as arteriovenous malformations, or AVMs), and also for occluding vessels that feed certain hyper-vascularised tumours, in order to starve the abnormal tissue and bring about its necrosis and shrinkage. One application of embolotherapy that is receiving increasing attention is the treatment of uterine fibroids. Uterine fibroids or leiomyomata are the most common tumour found in women. Fibroids are benign clonal tumours arising from the smooth-muscle cells of the uterus. Approximately 25% of premenopausal women suffer from fibroids, while the overall prevalence of these tumours could be as high as 77%. The incidence of fibroids in African-American women is three times that of Caucasian women. Fibroids may occur at any age, but are most common in women over the age of 40 years. After menopause, fibroids usually regress in size due to the lack of hormonal stimulation, which may result in infarction.

The rationale for utilizing embolisation to treat uterine fibroids can be traced to several known indications for embolotherapy. First, embolisation has been used with success as a palliative treatment in end-stage cancer patients for symptomatic relief. Examples of this include patients with bony metastases arising from renal cell carcinoma and patients with inoperable liver tumours (hepatoma and colon metastases). The reason why this procedure works in this scenario is because depriving a tumour of its blood supply ultimately decreases the size of the tumour, resulting in relief of mass-related symptoms. Second, embolisation has been shown to reduce

2

the vascularity of tumours prior to surgical excision thereby reducing intraoperative blood loss; this indication has been utilized for renal cell carcinomas and spinal tumours prior to resection. Third, embolisation has been used with success to control tumour-related bleeding in sites

5   throughout the body. Examples of this success include bleeding secondary to renal cell caricinoma, bladder tumours, angiomyolipoma, and hepatic adenomas. Finally, embolisation has been used with success to control abnormal uterine bleeding due to gynecologic malignancies (endometrial, cervical, and ovarian), postpartum bleeding, postsurgical bleeding, bleeding

10   from an ectopic pregnancy and bleeding due to congenital AV malformations. A recent article by Vedantham, *et al* Appl Radiol, 31(10):9-17, 2002, reviews the indications for uterine artery embolization in the obstetrical and gynecologic patient population.

In the major studies of uterine fibroid embolisation to date, the most

15   frequently used embolic material is particulate polyvinyl alcohol, which has been classified according to its particle size. The gel is delivered in suspension form in an aqueous vehicle, using a micocatheter, delivered to one or both of the uterine arteries.

One drawback to the UFE procedure is the associated pain that may

20   be experienced by the patient. For this reason, conscious sedation and analgesia are critical to the successful outcome of a UFE procedure. Not only does this help to reduce anxiety, but more specifically addresses the severe pelvic pain, cramps, and nausea that is termed postembolisation syndrome. Immediately following the UFE procedure, the patient can use an

25   analgesia pump to self-administer narcotic pain relief. Supplementation with systemic analgesics helps to reduce the amount of narcotic used by combatting pain and cramping. From four of the trials listed by Vedantham *et al*, despite high procedural success, pain is encountered as a major result.

Periprocedural pain control therefore, is of utmost importance since it

30   can represent the major morbidity of the procedure. Pain generally starts early after the embolisation and reaches the highest severity 24 to 48 hours

3

after the embolisation. Most pain protocols use a combination of opioids,
such as an oxycodone derivative, and a nonsteroidal anti-inflammatory
(NSAID), such as ibuprofen or ketorolac. Successful pain control potentially
allows this procedure to be performed on an outpatient basis. Early studies
5   attempting to perform UFE as an outpatient procedure reported that 15% of
patients returned to the hospital for pain control. One should not use intra-
arterial lidocaine in an attempt to reduce pain since it causes a large amount
of spasm (Keyoung JA, Levy EB, Roth AR, et al. Intraarterial lidocaine for
pain control after uterine artery embolization for leiomyomata. *J Vasc*
10   *Intervent Radiol.* 2001;12:1065-1069). Postembolization syndrome with
severe pain, fever, and an elevation in the white blood count occurs in as
many as 34% of patients. (Goodwin SC, McLucas B, Lee M, et al. Uterine
artery embolization for the treatment of uterine leiomyomata midterm results.
J Vasc Intervent Radiol. 1999;10:1159-1165).

15   Siskin *et al*, (Siskin GP, Stainken BF, Dowling K, *et al.* Outpatient
uterine artery embolization for symptomatic uterine fibroids: Experience in 49
patients. *J Vasc Intervent Radiol.* 2000;11:305-311) reported 95.9%
successful discharge after 8 hours of post-procedure observation. This
however, has been acknowledged as being a very complex pain-
20   management regime comprising of both intravenous IV and oral
administrations (Burbak F, *et al.* J Am Soc Gyn Laparoscopists 7(4), S1-49,
2000). They further elaborated on this atypical observation in (Siskin *et al*,
Techniques in Vascular and Interventional Radiology, 5(1), 35-43, 2002),
where they state that the management of pain varies so widely between
25   hospitals, that there is a medical need to keep the patients in hospital for
observation during the first 24-48hrs of pain treatment. The ability to
discharge patients within the same day is often impossible, and only
managed in that the procedure starts early morning, and finishes late in the
evening the same day. Observation by the hospital staff is required during
30   the PCA pump delivery of the opiate, and precludes early discharge.
Observations of procedures within a Hospital in the UK indicated that the low
4

incidence of UFE treatment was due to the availability of beds for the
hospital stay rather than the patients and Interventional Radiologist to carry
out the procedure.

Although UFE is considered very safe, any medical procedure has
5   some associated risks. Most patients feel cramping after UFE. The severity
of pain varies from patient to patient. Pain is related to the death of the
fibroid and to some degree the reduced blood supply (ischemia) to the
normal portion of the uterus. The pain is biphasic with the first 2-6 hours of
intense pain followed by a second phase of mild to moderate pain that can
10   be short or lasting up to several days. However, not every patient feels pain
after embolisation but it is reported to occur in 95% of patients.

The pain is treated actively by starting oral anti-inflammatory drugs 2
hours before the procedure and morphine after the procedure. The
morphine is administrated through a PCA (patient controlled analgesia)
15   pump. The patient can push a button to administer the medication in case of
pain. When the pain becomes tolerable, and after at least 4-6 hours of bed
rest, the patient can leave the hospital. Most of the time the patient spends
one night in the hospital.

Non Steroidal Anti-Inflammatory Drugs (NSAIDs) are medications
20   which, as well as having pain-relieving (analgesic) effects, have the effect of
reducing inflammation when used over a period of time.   A new class of
NSAIDs, cyclooxygenase-2 (COX-2) inhibitors, selectively inhibits
inflammatory prostaglandins (PGs). These new drugs have a lower
complication rate and do not tend to produce ulcers. There are many
25   different types of NSAIDs, including aspirin and other salicylates. Examples
include; ibuprofen (Motrin, Advil), naproxen (Naprosyn), diclofenac
(Voltaren), ketoprofen (Orudis), indomethacin (Indocin), and newer ones
such as celecoxib (Celebrex), the first COX-2 inhibitor on the market, and
rofecoxib (Vioxx), which was recently released:

Evolution of NSAIDs

The primary mechanism of action in NSAIDs is by interfering with the cyclooxygenase pathway (enzymes that make prostaglandins) and a resultant decrease in prostaglandin synthesis.

In the female reproductive tract NSAIDs are reported not only to inhibit endometrial prostaglandins, but also improve platelet aggregation and degranulation and increase uterine vasoconstriction in women with menorrhagia (van Eijkeren JJ, 1992). Prostaglandins are active mediators of the inflammatory cascade, which also serve to sensitize peripheral nociceptors (nerve endings). Recent research (Tannenbaum H 1996, Vane JR 1996, Emery P 1996) has shown that there are two types of cyclooxygenase, denoted COX-1 and COX-2. Each type of cyclooxygenase lends itself to producing different types of prostaglandins.

6

There are two types of prostaglandins.

The first type comprises maintenance prostaglandins. These are made regularly by the body, are produced by COX-1 enzyme and play a role in maintaining normal function in several organ systems. Examples of

5   maintenance effect in some organs are the protective lining of the stomach, normal platelet function and kidney blood flow.

The second class of prostaglandins are "inflammatory". They are produced by the body in response to an inflammatory stimulus and are produced by COX-2 enzyme. They play a role in causing inflammation and

10   pain.

As mentioned above, there are two types of cyclooygenase enzyme. COX-1 is stimulated continuously by normal body physiology. The COX-1 enzyme is constitutive, meaning that its concentration in the body remains stable. It is present in most tissues and converts arachidonic acid into

15   prostaglandins. The location of the COX-1 enzyme dictates the function of the prostaglandins it releases (Vane JR 1996). For example, COX-1 in the stomach wall produces prostaglandins that stimulate mucous production. COX-1 performs a housekeeping function to synthesize PGs which regulate normal cell activity

20   COX-2, in contrast to COX-1, is induced in most parts of the body. It is not normally present in cells but its expression can be increased dramatically by the action of macrophages the scavenger cells of the immune system (Tannenbaum H, 1996). COX-2's most important role is in inflammation. COX-2 is involved in producing prostaglandins for an

25   inflammatory response. Cyclooxygenase-2 (COX-2), known to be elevated in several human cancers, regulates angiogenesis by inducing production of angiogenic factors (Fujiwaki R, 2002). COX-2 is constitutive in the kidney, ovary, uterus and brain. There is believed to be a link between cancer of the uterus and the COX-2 enzyme. COX-2 and its product prostaglandins

30   set off a cascade of molecular events, including an abnormal increase in estrogen, that leads to tumor growth. Differential COX localization and PG

release in Thy-1(+) and Thy-1(-) human female reproductive tract has been reported. COX-2, which is generally considered an inducible form, in the female reproductive tract is constitutively expressed in Thy-1 (-) fibroblast subset, which minimally produces PGE (2). And Thy-1 (+) fibroblasts highly express COX-1, which is responsible for the high-level PGE (2) production, a feature usually attributed to COX-2 (Koumas L, 2002).

Inhibitors of COX have activities against both enzymes but many are selective to one or other of the enzymes.

Inhibitors with high COX-1 selectivity are found to have undesirable side effects on the G1 tract, manifest when delivered orally. The recently launched COX-2 selective inhibitors reduce such side effects when administered orally.

Fibroids are commonly found in women with menorrhagia (an excessive abnormal uterine bleeding) and fibroids of the submucosal type in particular have been associated with menorrhagia. Menorrhagia is characterized by either heavy menstrual bleeding or prolonged menstrual bleeding. Women with fibroids might discharge such heavy volumes of blood during their period that they have to constantly change sanitary protection. At the same time, whereas most women have periods that last 4 to 5 days, a woman with fibroids may bleed for over a week.

Dysmenorrhea is divided into two types: primary (affect young teens) and secondary dysmenorrhea (older women). Both types include the following symptoms: backache, diarrhea, dizziness, headache, nausea, vomiting, and tenseness. Fibroids are one of the conditions which often causes or sparks the development of secondary dysmenorrhea (Gynecological Health Center (B), 1).

Short courses of ibuprofen were successful in reducing pain in pregnant women with painful uterine leiomyomas (Katz VL, 1989). It was reported to suppress menstrual $PGF2\alpha$ release far more than PGE2 compared naproxen, which equally suppressed both types of PGs. Selectivity for $PGF2\alpha$ is suggested to reduce risks of closure of the fetal

8

ductus arteriosus linked to pre-mature labor (Chan WY, 1983, Powell AM, 1984, Chan WY, 1981). Reduction of intra-uterine pressure and pain intensity by using ibuprofen in a dysmenorrhoeic patient has been reported (Milsom I, 1985, Milsom I, 1984, Chan WY, 1983). Ibuprofen, mefenamic

5   acid and naproxen significantly reduced bleeding in women with menorrhagia by 30-50% (Anderson ABM, 1976 and Makarainen L, 1986). Clinical relief of the dysmenorrhoeic symptoms by ibuprofen accompanies the reduction of menstrual fluid prostaglandin (Dawood My, 1981). Ibuprofen 1200 mg/day reduced (P less than 0.01) median blood loss in

10   primary menorrhagia, but had no effect on blood loss in women with uterine fibroids and factor VIII deficiency (Makarainen L, Ylikorkala O, 1986). There is a failure rate of~20-25% of using NSAIDs in treatment of dysmenorrhea (Wilson ML, 2001). Their mode of action is thought to be by inhibiting endometrial synthesis of prostaglandins (Sanfilippo Js, 1983).

15   According to the present invention there is provided a new use of polymer and, associated with polymer in a releasable form, a pharmaceutically active agent which is a non-steroidal anti-inflammatory agent, in the manufacture of a composition for use in a method of uterine fibroid embolisation, in which the pharmaceutical active is released from the

20   polymer at the site of embolisation.

The active may alternatively be defined as a COX inhibitor.

The invention allows local delivery of appropriate pharmaceutical agents for pain relief and/or antiinflammatory treatment of uterine fibroids via a polymer-based embolic agent. The polymer is a water-insoluble material.

25   Although it may be biodegradable, so that drug may be released substantially by erosion of polymer matrix to release drug from the surface, preferably the polymer is substantially biostable. It is preferred for the polymer to be water-swellable.

Water-swellable polymer useful in the invention preferably has a

30   equilibrium water content, when swollen in water at 37°C, measured by gravimetric analysis, in the range of 40 to 99 wt%, preferably 75 to 95%.

9

The polymer may be in the form of a coating on an embolic device · such as a metal coil. Preferably, however, the embolic agent is in the form of particles of bulk polymer, or alternatively foamed polymer, having open or closed cells therein. Alternatively, the polymeric agent may be formed *in*

5   *situ*, by delivery of a liquid agent and curing at the site of embolisation to form an insoluble polymer matrix.

In the preferred embodiment of the invention, the composition which is administered to a patient in need of embolisation therapy, is in the form of a suspension of particles of water-swollen water-insoluble polymer.

10   Preferably the particles are graded into calibrated size ranges for accurate embolisation of vessels. The particles preferably have sizes when equilibrated in water at 37°C, in the range 40 to 1500 μm, more preferably in the range 100 to 1200 μm. The calibrated ranges may comprise particles having diameters with a bandwidth of about 100 to 300 μm. The size ranges

15   may be for instance 100 to 300 μm, 300 to 500 μm, 500 to 700 μm, 700 to 900 μm and 900 to 1200 μm. Preferably the particles are substantially spherical in shape. Such particles are referred to herein as microspheres.

Generally the polymer is covalently crosslinked, although it may be appropriate for the polymer to be ionically crosslinked, at least in part. The

20   polymer may be formed by polymerising ethylenically unsaturated monomers · in the presence of di- or higher-functional crosslinking monomers, the · ethylenically unsaturated monomers preferably including an ionic (including zwitterionic) monomer. Copolymers of hydroxyethyl methacrylate, acrylic acid and cross-linking monomer, such as ethylene glycol dimethacrylate or

25   methylene bisacrylamide, as used for etafilcon A based contact lenses may be used.

Another type of polymer which may be used to form the water-swellable water-insoluble matrix is polyvinyl alcohol crosslinked using aldehyde type crosslinking agents such as glutaraldehyde. For such

30   products, the polyvinyl alcohol (PVA) may be rendered ionic. For instance the PVA may be rendered ionic by providing pendant ionic groups by

reacting a functional ionic group containing compound with the hydroxyl

groups. Examples of suitable functional groups for reaction with the

hydroxyl groups are acylating agents, such as carboxylic acids or derivatives

thereof, or other acidic groups which may form esters.

5   The invention is of particular value where the polymer matrix is

formed of a polyvinyl alcohol macromer, having more than one ethylenically

unsaturated pendant group per molecule, by radical polymerisation of the

ethylenic groups. Preferably the PVA macromer is copolymerised with

ethylenically unsaturated monomers for instance including a nonionic and/or

10   ionic monomer.

The PVA macromer may be formed, for instance, by providing PVA

polymer, of a suitable molecular weight such as in the range 1000 to

500,000 D, preferably 10,000 to 100,000 D, with pendant vinylic or acrylic

groups. Pendant acrylic groups may be provided, for instance, by reacting

15   acrylic or methacrylic acid with PVA to form ester linkages through some of

the hydroxyl groups. Other methods for attaching vinylic groups capable of

polymerisation onto polyvinyl alcohol are described in, for instance, US

4,978,713 and, preferably, US 5,508,317 and 5,583,163. Thus the preferred

macromer comprises a backbone of polyvinyl alcohol to which is linked, via a

20   cyclic acetal linkage, an (alk)acrylaminoalkyl moiety. Example 1 describes

the synthesis of an example of such a macromer known by the approved

named nelfilcon B. Preferably the PVA macromers have about 2 to 20

pendant ethylenic groups per molecule, for instance 5 to 10.

Where PVA macromers are copolymerised with ethylenically

25   unsaturated monomers including an ionic monomer, the ionic monomer

preferably has the general formula I

$$Y^1BQ$$

30   in which Y^1 is selected from
$CH_2=C(R)-CH_2-O-$, $CH_2=C(R)-CH_2\ OC(O)-$, $CH_2=C(R)OC(O)-$, $CH_2=C(R)-O-$,
$CH_2=C(R)CH_2OC(O)N(R^1)-$, $R^2OOCCR=CRC(O)-O-$, $RCH=CHC(O)O-$,
$RCH=C(COOR^2)CH_2-C(O)-O-$,

and

wherein:

R is hydrogen or a C_1-C_4 alkyl group;

R^1 is hydrogen or a C_1-C_4 alkyl group;

R^2 is hydrogen or a C_{1-4} alkyl group or BQ where B and Q are as
defined below;

A is $-O-$ or $-NR^1-$;

K^1 is a group $-(CH_2)_rOC(O)-$, $-(CH_2)_rC(O)O-$, $-(CH_2)_rOC(O)O-$,
$-(CH_2)_rNR^3-$, $-(CH_2)_rNR^3C(O)-$, $-(CH_2)_rC(O)NR^3-$, $-(CH_2)_rNR^3C(O)O-$,
$-(CH_2)_rOC(O)NR^3-$, $-(CH_2)_rNR^3C(O)NR^3-$ (in which the groups R^3 are the
same or different), $-(CH_2)_rO-$, $-(CH_2)_rSO_3$ $-$, or, optionally in combination with
B^1, a valence bond and r is from 1 to 12 and R^3 is hydrogen or a C_1-C_4 alkyl
group;

B is a straight or branched alkanediyl, oxaalkylene,
alkanediyloxaalkanediyl, or alkanediyloligo(oxaalkanediyl) chain optionally
containing one or more fluorine atoms up to and including perfluorinated
chains or, if Q or Y^1 contains a terminal carbon atom bonded to B a valence
bond; and

Q is an ionic group.

12

An anionic group Q may be, for instance, a carboxylate, carbonate, sulphonate, sulphate, nitrate, phosphonate or phosphate group. The monomer may be polymerised as the free acid or in salt form. Preferably the pK_a of the conjugate acid is less than 5.

A suitable cationic group Q is preferably a group $N^+R^4_3$, $P^+R^5_3$ or $S^+R^5_2$ in which the groups R^4 are the same or different and are each hydrogen, C_{1-4}-alkyl or aryl (preferably phenyl) or two of the groups R^4 together with the heteroatom to which they are attached from a saturated or unsaturated heterocyclic ring containing from 5 to 7 atoms the groups R^5 are each OR^4 or R^4. Preferably the cationic group is permanently cationic, that is each R^4 is other than hydrogen. Preferably a cationic group Q is $N^+R^4_3$ in which each R^4 is C_{1-4}-alkyl, preferably methyl.

A zwitterionic group Q may have an overall charge, for instance by having a divalent centre of anionic charge and monovalent centre of cationic charge or vice-versa or by having two centres of cationic charge and one centre of anionic charge or vice-versa. Preferably, however, the zwitterion has no overall charge and most preferably has a centre of monovalent cationic charge and a centre of monovalent anionic charge.

Examples of zwitterionic groups which may be used as Q in the present invention are disclosed in WO-A-0029481.

Where the ethylenically unsaturated monomer includes zwitterionic monomer, for instance, this may increase the hydrophilicity, lubricity, biocompatibility and/or haemocompatibility of the particles. Suitable zwitterionic monomers are described in our earlier publications WO-A-9207885, WO-A-9416748, WO-A-9416749 and WO-A-9520407. Preferably a zwitterionic monomer is 2-methacryloyloxy-2'-trimethylammonium ethyl phosphate inner salt (MPC).

In the monomer of general formula I preferably Y^1 is a group $CH_2=CRCOA-$ in which R is H or methyl, preferably methyl, and in which A is preferably NH. B is preferably an alkanediyl group of 1 to 12, preferably 2 to 6 carbon atoms. Such monomers are acrylic monomers.

13

There may be included in the ethylenically unsaturated monomer diluent monomer, for instance non-ionic monomer. Such monomer may be useful to control the pK_a of the acid groups, to control the hydrophilicity or hydrophobicity of the product, to provide hydrophobic regions in the polymer,

5   or merely to act as inert diluent. Examples of non-ionic diluent monomer are, for instance, alkyl (alk) acrylates and (alk) acrylamides, especially such compounds having alkyl groups with 1 to 12 carbon atoms, hydroxy, and di-hydroxy-substituted alkyl(alk) acrylates and -(alk) acrylamides, vinyl lactams, styrene and other aromatic monomers.

10   In the polymer matrix, where there is ionic group present the level of ion is preferably in the range 0.1 to 10 meq g^{-1}, preferably at least 1.0 meq g^{-1}.

Where PVA macromer is copolymerised with other ethylenically unsaturated monomers, the weight ratio of PVA macromer to other monomer

15   is preferably in the range of 50:1 to 1:5, more preferably in the range 20:1 to 1:2. In the ethylenically unsaturated monomer the ionic monomer is preferably present in an amount in the range 10 to100 mole%, preferably at least 25 mole%.

The polymer may be formed into particles in several ways. For

20   instance, the crosslinked polymer may be made as a bulk material, for instance in the form of a sheet or a block, and subsequently be comminuted to the desired size. Alternatively, the crosslinked polymer may be formed as such in particulate form, for instance by polymerising in droplets of monomer in a dispersed phase in a continuous immiscible carrier. Examples of

25   suitable water-in-oil polymerisations to produce particles having the desired size, when swollen, are known. For instance US 4,224,427 describes processes for forming uniform spherical beads (microspheres) of up to 5 mm in diameter, by dispersing water-soluble monomers into a continuous solvent phase, in a presence of suspending agents. Stabilisers and surfactants may

30   be present to provide control over the size of the dispersed phase particles. After polymerisation, the crosslinked microspheres are recovered by known

14

means, and washed and optionally sterilised. Preferably the particles eg microspheres, are swollen in an aqueous liquid, and classified according to their size.

In the invention the pharmaceutically active agent is a non-steroidal
5   antiinflammatory drug (NSAID). It may alternatively be defined as a COX inhibitor. The reasons for the intense pain following UFE are not currently well understood, but cells in the region of the ischemic and necrosing tissues may release a host of inflammatory markers that may give rise to prostaglandin synthesis and ensuing signalling of pain. These actives are
10   useful as both analgesics and anti-inflammatories and thus may have a synergistic role in reducing both the cause and the effect of pain post embolisation.

Examples of specific active agents useful in the present invention are:

celecoxib (Celebrex)
15   rofecoxib (Vioxx)
diclofenac (Voltaren, Cataflam)
diflunisal (Dolobid)
etodolac (Lodine)
flurbiprofen (Ansaid)
20   ibuprofen (Motrin, Advil)
indomethacin (Indocin)
ketoprofen (Orudis, Oruvail)
ketorolac (Toradol)
nabumetone (Relafen)
25   naproxen (Naprosyn, Alleve)
oxaprozin (Daypro)
piroxicam (Feldene)
sulindac (Clinoril)
tolmetin (Tolectin)
30   The active agent is preferably a COX inhibitor. It may be selective for COX-1. The invention allows local delivery of the active to the site of

15

embolisation, and the target fibroids. This avoids systemic delivery and the associated side effects described above with such actives, exhibited especially when the active is administered orally.

The active may be COX-2 selective. Since COX-2 inhibitors are
5 expected to inhibiti nflammation and inflammation may be induced by embolisation and hence be the cause of pain, such inhibitors are expected to be effective when delivered locally in the invention to the embolus, in the vicinity of the uterine fibroids.

Suitable COS selective inhibitors are shown in the following table:

10

16

Log [IC$_{80}$ ratio WHMA COX-2/COX-1)]	Drugs
-2 to -1	DFP
	L-745337
	Rofecoxib
	NS398
	Etodolac
-1 to 0	Meloxicam
	Celecoxib
	Nimesulide
	Diclofenac
	Sulindac Sulphide
	Meclofenamate
	Tomoxiprol
	Piroxicam
	Diflunisal
	Sodium Salicylate
0	Niflumic Acid
	Zomepirac
	Fenoprofen
0 to 1	Amypyrone
	Ibuprofen
	Tolmetin
	Naproxen
	Aspirin
	Indomethacin
	Ketoprofen
1 to 2	Suprofen
	Flurbiprofen
2 to 3	Ketorolac

WHMA = William Harvey Human Modified Whole Blood Assay

The table refers to the Log [IC$_{80}$ ratio WHMA COX-2/COX-1)] for the

agents which have been assayed by William Harvey Human Modified Whole

17

Blood Assay. Those drugs with a "0" value indicate equal potency, i.e. an
IC_{80} ratio of 1. Values above "0" indicates the drug is more selective to COX-
1 and values below "0" indicates the drug is more selective to COX-2.

DFP is Di isopropylphosphofluoridate

5   L-745337 is 5-methanesulphonamide-6-(2,4-difluorothiophenyl)-1-
indanone.

Values from Warner T.D. et al, Proc. Natl. Acad. Sci (1999) 96, 7563.

In a further aspect of the invention there is provided a new
pharmaceutical composition comprising microspheres for water-insoluble,
10   water-swellable polymer formed by the radical polymerisation of poly(vinyl
alcohol) macromer having pendant ethylenically unsaturated groups and,
associated with the polymer in releasable form, a pharmaceutically active
agent which is a non-steroidal anti inflammatory agent and/or which is a
COX inhibitor.

15   The active in this aspect is preferably a COX inhibitor, as described
above in connection with the first aspect of the invention. The polymer is
preferably as described above in connection with the preferred embodiment
of the invention.

The pharmaceutical agent is associated with the polymer preferably
20   so as to allow controlled release of the agent over a period. Where the
agent is for reducing inflammation and pain relief this period may be up to a
few days, preferably up to 72 hours when most postoperative pain is
experienced. The agent may be electrostatically, or covalently bonded to
the polymer or held by Vander Waal's interactions.

25   The pharmaceutical active may be incorporated into the polymer
matrix by a variety of techniques. In one method, the active may be mixed
with a precursor of the polymer, for instance a monomer or macromer
mixture or a cross-linkable polymer and cross-linker mixture, prior to
polymerising or crosslinking. Alternatively, the active may be loaded into the
30   polymer after it has been crosslinked. For instance, particulate dried
polymer may be swollen in a solution of active, preferably in water or in an

18

alcohol such as ethanol, optionally with subsequent removal of non-absorbed agent and/or evaporation of solvent. A solution of the active, in an organic solvent such as an alcohol, or, more preferably, in water, may be sprayed onto a moving bed of particles, whereby drug is absorbed into the

5   body of the particles with simultaneous solvent removal. Most conveniently, we have found that it is possible merely to contact swollen particles suspended in a continuous liquid vehicle, such as water, with an aqueous alcoholic solution of drug, over a period, whereby drug becomes absorbed into the body of the particles. Techniques to fix the drug in the particles may

10   increase loading levels, for instance precipitation by shifting the pH of the loading suspension to a value at which the active is in a relatively insoluble form. The swelling vehicle may subsequently be removed or, conveniently, may be retained with the particles as part of the product for subsequent use as an embolic agent or the swollen particles may be used in swollen form in

15   the form of a slurry, i.e. without any or much liquid outside the swollen particles.

Alternatively, the suspension of particles can be removed from any remaining drug loading solution and the particles dried by any of the classical techniques employed to dry pharmaceutical -based products. This

20   could include, but is not limited to, air drying at room or elevated temperatures or under reduced pressure or vacuum; classical freeze-drying; atmospheric pressure-freeze drying; solution enhanced dispersion of supercritical fluids (SEDS). Alternatively the drug-loaded microspheres may be dehydrated using an organic solvent to replace water in a series of

25   steps, followed by evaporation of the more volatile organic solvent. A solvent should be selected which is a non-solvent for the drug.

In brief, a typical classical freeze drying process might proceed as follows: the sample is aliquoted into partially stoppered glass vials, which are placed on a cooled, temperature controlled shelf within the freeze dryer.

30   The shelf temperature is reduced and the sample is frozen to a uniform, defined temperature. After complete freezing, the pressure in the dryer is

lowered to a defined pressure to initiate primary drying. During the primary drying, water vapour is progressively removed from the frozen mass by sublimation whilst the shelf temperature is controlled at a constant, low temperature. Secondary drying is initiated by increasing the shelf

5　temperature and reducing the chamber pressure further so that water absorbed to the semi-dried mass can be removed until the residual water content decreases to the desired level. The vials can be sealed, *in situ*, under a protective atmosphere if required.

　　Atmospheric pressure freeze drying is accomplished by rapidly

10　circulating very dry air over a frozen product. In comparison with the classical freeze-drying process, freeze-drying without a vacuum has a number of advantages. The circulating dry gas provides improved heat and mass transfer from the frozen sample, in the same way as washing dries quicker on a windy day. Most work in this area is concerned with food

15　production, and it has been observed that there is an increased retention of volatile aromatic compounds, the potential benefits of this to the drying of biologicals is yet to be determined. Of particular interest is the fact that by using atmospheric spray drying processes instead of a cake, a fine, free-flowing powder is obtained. Particles can be obtained which have submicron

20　diameters, this is tenfold smaller than can be generally obtained by milling. The particulate nature, with its high surface area results in an easily rehydratable product, currently the fine control over particle size required for inhalable and transdermal applications is not possible, however there is potential in this area.

25　　In a further aspect of the inevntion there is provided a new method of loading a non-steroidal anti-inflammatory agent which has an acid group into a water-insoluble, water swellable polymer vehicle including the steps of

　　a)　contacting water-swellable cross-linked poly(vinyl alcohol) with polymer an aqueous solution of the agent at a pH at above the pKa of the

30　acid group,

　　b)　adding acid to the product of step a) so as to reduce the pH of

20

the aqueous liquid in contact with polymer to below the pKa of the acid group; and

c)   recovering the polymer with loaded agent in free acid form.

Although the product of this method may be used to deliver the active by methods other than embolisation and for indications other than uterine fibroid treatment these are the preferred uses.

The new method of this aspect of the invention is of value for the COX inhibitors mentioned above whose free acid form, which is to be the form of the administered compound, is relatively water-insoluble. Such compounds include napoxen, ulindac, diclofenac, indomethacin, ibuprofen, acetyl salicylate, ketorolac, ketoprofen, flurbiprofen and suprofen, preferably ibuprofen.

Preferably the pH of the aqueous solution in step a) is at least 5, and the pH of the liquid after step b) is less than 3, as the acid group is a carboxylic acid in all these compounds.

The embolic compositions of the invention may be administered in the normal manner for UFE. Thus the composition may be admixed immediately before administration by the interventional radiologist, with imaging agents such as radiopaque agents. Alternatively or additionally, the particles may be preloaded with radiopaque material in addition to the pharmaceutical active. Thus the polymer and pharmaceutical active, provided in preformed admixture, may be mixed with a radiopaque imaging agent in a syringe, used as the reservoir for the delivery device. The composition may be administered, for instance, from a microcatheter device, into the uterine arteries. Selection of suitable particle size range, dependent upon the desired site of embolisation may be made in the normal way by the interventional radiologists.

The example is illustrated in the following examples and figures, in which

Example 1: Outline Method for the Preparation of Microspheres

Nelfilcon B macromer synthesis:

The first stage of microsphere synthesis involves the preparation of
Nelfilcon B - a polymerisable macromer from the widely used water soluble
polymer PVA. Mowiol 8-88 poly(vinyl alcohol) (PVA) powder (88%
hydrolised, 12% acetate content, average molecular weight about 67,000D)
(150g) (Clariant, Charlotte, NC USA) is added to a 2l glass reaction vessel.
With gentle stirring, 1000ml water is added and the stirring increased to
400rpm. To ensure complete dissolution of the PVA, the temperature is
raised to 99 ±9°C for 2-3 hours. On cooling to room temperature N-
acryloylaminoacetaldehyde (NAAADA) (Ciba Vision, Germany) (2.49g or
0.104mmol/g of PVA) is mixed in to the PVA solution followed by the addition
of concentrated hydrochloric acid (100ml) which catalyses the addition of the
NAAADA to the PVA by transesterification. The reaction proceeds at room
temperature for 6-7 hours then stopped by neutralisation to pH 7.4 using
2.5M sodium hydroxide solution. The resulting sodium chloride plus any
unreacted NAAADA is removed by diafiltration (step 2).

Diafiltration of macromer:

Diafiltration (tangential flow filtration) works by continuously
circulating a feed solution to be purified (in this case nelfilcon B solution)
across the surface of a membrane allowing the permeation of unwanted
material (NaCl, NAAADA) which goes to waste whilst having a pore size
small enough to prevent the passage of the retentate which remains in
circulation.

Nelfilcon B diafiltration is performed using a stainless steel Pellicon 2
Mini holder stacked with 0.1m² cellulose membranes having a pore size with
a molecular weight cut off of 3000 (Millipore Corporation, Bedford, MA USA).
Mowiol 8-88 has a weight average molecular weight of 67000 and therefore

23

has limited ability to permeate through the membranes.

The flask containing the macromer is furnished with a magnetic stirrer bar and placed on a stirrer plate. The solution is fed in to the diafiltration assembly via a Masterflex LS peristaltic pump fitted with an Easy Load II

5   pump head and using LS24 class VI tubing. The Nelfilcon is circulated over the membranes at approximately 50psi to accelerate permeation. When the solution has been concentrated to about 1000ml the volume is kept constant by the addition of water at the same rate that the filtrate is being collected to waste until 6000ml extra has been added. Once achieved, the solution is

10   concentrated to 20-23% solids with a viscosity of 1700-3400 cP at 25°C. Nelfilcon is characterised by GFC, NMR and viscosity.

Microsphere Synthesis:

The spheres are synthesised by a method of suspension polymerisation in which an aqueous phase (nelfilcon B) is added to an

15   organic phase (butyl acetate) where the phases are immiscible. By employing rapid mixing the aqueous phase can be dispersed to form droplets, the size and stability of which can be controlled by factors such as stirring rates, viscosity, ratio of aqueous/organic phase and the use of stabilisers and surfactants which influence the interfacial energy between

20   the phases. Two series of microspheres are manufactured, a low AMPS and a higher AMPS series, the formulation of which are shown below.

A   High AMPS:

Aqueous: ca 21% w/w Nelfilcon B solution (400 ±50g approx)

ca 50% w/w 2-acrylamido-2-methylpropanesulphonate Na salt

25   (140 ±10g)

Purified water (137±30g)

Potassium persulphate (5.22±0.1g)

Tetramethyl ethylene diamine TMEDA (6.4±0.1ml)

Organic: n-Butyl acetate (2.7 ±0.3L)

30   10% w/w cellulose acetate butyrate in ethyl acetate (46±0.5g)

Purified water (19.0 ±0.5ml)

24

B   Low AMPS:

Aqueous: ca 21% w/w Nelfilcon B solution (900 ±100g approx)

ca 50% w/w 2-acryamido-2-methylpropanesulphonate Na salt

(30.6 ±6g)

5   Purified water (426±80g)

Potassium persulphate (20.88±0.2g)

TMEDA (25.6±0.5ml)

Organic: n-Butyl acetate (2.2 ±0.3L)

10% w/w cellulose acetate butyrate (CAB) in ethyl acetate

10   (92±1.0g)

Purified water (16.7 ±0.5ml)

A jacketed 4000ml reaction vessel is heated using a computer

controlled bath (Julabo PN 9-300-650) with feedback sensors continually

monitoring the reaction temperature.

15   The butyl acetate is added to the reactor at 25°C followed by the CAB

solution and water. The system is purged with nitrogen for 15 minutes

before the PVA macromer is added. Cross linking of the dispersed PVA

solution is initiated by the addition of TMEDA and raising the temperature to

55°C for three hours under nitrogen. Crosslinking occurs via a redox

20   initiated polymerisation whereby the amino groups of the TMEDA react with

the peroxide group of the potassium persulphate to generate radical species.

These radicals then initiate polymerisation and crosslinking of the double

bonds on the PVA and AMPS transforming the dispersed PVA-AMPS

droplets into insoluble polymer microspheres. After cooling to 25°C the

25   product is transferred to a filter reactor for purification where the butyl

acetate is removed by filtration followed by:

- Wash with 2 x 300ml ethyl acetate to remove butyl acetate and
  CAB

- Equilibrate in ethyl acetate for 30mins then filtered

30   - Wash with 2 x 300 ml ethyl acetate under vacuum filtration

- Equilibrate in acetone for 30mins and filter to remove ethyl

acetate, CAB and water

- Wash with 2 x 300ml acetone under vacuum filtration
- Equilibrate in acetone overnight
- Wash with 2 x 300ml acetone under vacuum
- Vacuum dry, 2hrs, 55°C to remove residual solvents.

Dyeing:

This step is optional but generally unnecessary when drug is loaded with a coloured active (as this provides the colour). When hydrated the microsphere contains about 90% (w/w) water and can be difficult to visualise. To aid visualisation in a clinical setting the spheres are dyed blue using reactive blue #4 dye (RB4). RB4 is a water soluble chlorotriazine dye which under alkaline conditions will react with the pendant hydroxyl groups on the PVA backbone generating a covalent ether linkage. The reaction is carried out at pH12 (NaOH) whereby the generated HCl will be neutralised resulting in NaCl.

Prior to dyeing, the spheres are fully re-hydrated and divided into 35g aliquots (treated individually). Dye solution is prepared by dissolving 0.8g RB4 in 2.5M NaOH solution (25ml) and water (15ml) then adding to the spheres in 2l of 80g/l⁻¹ saline. After mixing for 20mins the product is collected on a 32 μm sieve and rinsed to remove the bulk of the unreacted dye.

Extraction:

An extensive extraction process is used to remove any unbound or non specifically adsorbed RB4. The protocol followed is as shown:

- Equilibrate in 2l water for 5mins. Collect on sieve and rinse. Repeat 5 times
- Equilibrate in 2l solution of 80mM disodium hydrogen phosphate in 0.29% (w/w) saline. Heat to boiling for 30mins. Cool, collect on sieve and wash with 1l saline. Repeat twice more.
- Collect, wash on sieve the equilibrate in 2l water for 10mins.

26

- Collect and dehydrate in 1l acetone for 30mins.
- Combine all aliquots and equilibrate overnight in 2l acetone.

Sieving:

The manufactured microsphere product ranges in size from 100 to 1200 microns and must undergo fractionation through a sieving process using a range of mesh sizes to obtain the nominal distributions listed below.

1.   100 – 300µm
2.   300 – 500µm
3.   500 – 700µm
4.   700 – 900µm
5.   900 – 1200µm

Prior to sieving the spheres are vacuum dried to remove any solvent then equilibrated at 60°C in water to fully re-hydrate. The spheres are sieved using a 316L stainless steel vortisieve unit (MM Industries, Salem Ohio) with 15" stainless steel sieving trays with mesh sizes ranging from 32 to 1000µm. Filtered saline is recirculated through the unit to aid fractionation. Spheres collected in the 32micron sieve are discarded.

Example 2:   Uptake and Elution of Ibuprofen in Low AMPS and High AMPS Microspheres

Two solutions were prepared, one 2.5 mg per ml of ibuprofen (in phosphate buffer solution), the second 2.5 mg per ml in ethanol. Standard curves of both solutions were measured by UV absorption at 250 nm.

In PBS it gave Absorbance = 1.2689 x Concentration – 0.0096

In ethanol it gave Absorbance = 0.6875 x Concentration + 0.0329

These standard curves were used to monitor the uptake of drug by the microspheres.

For each of the Low AMPS and High AMPS microspheres four 1 ml syringes were filled with 0.25 ml of microspheres. Two glass vials were charged with 5 ml of the 2.5 mg/ml drug in PBS and a further two vials with 5 ml of PBS to act as controls. This was repeated for the drug in ethanol and two control vials of 5 ml of ethanol, again for controls. Taking two of the Low

AMPS microsphere filled syringes, the contents of one was added to the vial containing drug solution in PBS and the second syringe added to its equivalent control vial. This was repeated for two of the High AMPS microsphere filled syringes. The whole process was then repeated with the

5   ethanol solutions.

Uptake of ibuprofen was monitored using 1 ml of solution, replaced each time to keep the concentration constant, by UV spectrometry at 250 nm. The resulting absorbencies were used to calculate the amount of drug loaded in mg per ml of microspheres.

10   Absorbance (solution) – Absorbance of control = Actual Absorbance of drug loaded.

Concentration was calculated using the relevant standard curve and converted to give the concentration of drug which could be loaded into 1 ml of microspheres.

15   The results of the uptake from PBS over a period of one day are shown in Figure 1. The results of the uptake from ethanol are shown in Figure 2.

Release of ibuprofen from the ethanol loaded low AMPS microspheres were made in 5 ml PBS and monitored over 7 days.

20   Concentrations were calculated using the PBS standard curve. The results are shown in Figure 3 which shows the percentage of the total released over the 7 day period.

Example 3 : Loading and Release of Flurbiprofen from Microspheres

25   A solution of 100mg/ml flurbiprofen (Sigma) in ethanol was prepared. 5 ml of the solution was added to 0.5 ml of microspheres/beads of the present invention, made as outlined in example 1. Low AMPS and high AMPS microspheres of size 500-710µm were used and drug uptake monitored by UV. The samples were agitated on a roller mixer. Aliquots of

30   supernatant were taken at 10, 20, 30, 60 mins and then at 2hr, out to 24hr. Uptake was calculated from the flurbiprofen remaining in solution. Both

types of the microspheres were loaded with similar doses of 195mg (low AMPS) and 197 (high AMPS bead) per ml of hydrated microspheres (Fig 4), and in less than 30 minutes, 99% of the drug solution is located in the microspheres. Microspheres of the present invention of each size loaded with 200mg/ml flurbiprofen were placed in 250ml water at 37°C. 30% release was achieved in first 10 minutes with a further 5% in 2 days.. If microspheres were transferred to 100ml of elutant, release was slow until eventually equilibrium was reached (Fig 5).

Example 4: Loading and Release of Diclofenac from Microspheres

A solution of 100mg/ml diclofenac (Sigma) in ethanol was prepared. 5 ml of the solution was added to 0.5 ml of low AMPS and high AMPS microspheres of the present invention produced as outlined in example 1; both samples used microspheres having size range 500-710µm, and uptake monitored by UV. The samples were agitated on a roller mixer. Aliquots of supernatant were taken at 5,15, 30 and 240 mins and then 24hr. Uptake was calculated from the diclofenac remaining in solution. Both types of the microspheres were loaded with similar doses of 26mg (low AMPS beads) and 30mg (high AMPS beads) per ml of hydrated microspheres (Fig 6), and in less than 30 minutes, 99% of the drug solution is located in the microspheres. Microspheres of the present invention of each size loaded with 26 and 30mg/ml diclofenac were placed in 250ml water at 37°C. 18-26% release in first 5 minutes with a further 35% in 48hrs (Fig 7).

Example 4: Loading and Release of Ketorolac from Microspheres

Two solutions of 50mg/ml and 10mg/ml ketorolac (Sigma) in water were prepared. 5 ml of the solution was added to 0.5 ml of low AMPS microspheres, of size 500-710µm, and uptake monitored by HPLC. The samples were agitated on a roller mixer. Aliquots of supernatant were taken at 5,10,20 40 and 60 mins and then 24hr. Uptake was calculated from the ketorolac remaining in solution. The microspheres were loaded with similar approximately doses half the concentrations of the original loading solutions

29

per ml of hydrated microspheres (Fig 8), and in less than 10 minutes, 99% of the drug solution is located in the microspheres. Microspheres of each type loaded with 13 mg and 27mg/ml ketorolac were placed in 250ml water at 37°C. From the high AMPS loaded microspheres 43% released in first 5

5 minutes with a 90% in 1hrs this was followed with a slow release of a further 4% in the next 24 hrs (Fig 9). The low loaded microspheres showed a similar profile with a higher amount of ketorolac 75% released in first 5 minutes, 90% in 1 hr and a further 5% in next 24 hrs.

Example 5: Loading and Release of Ibuprofen Free Acid from

10   **Microspheres**

A series of experiments were carried out, using a loading solution containing 250mg/ml solution of Ibuprofen free acid (Sigma) in ethanol (Romil). 2ml of this solutions was added to 1 ml of hydrated low AMPS microspheres made as described in example 1, and uptake monitored by UV

15 of the supernatant at 263nm. The samples were agitated on a roller mixer. Samples of the supernatant were taken at 10, 20, 40, 60 mins and 24hrs. Uptake was calculated from the ibuprofen remaining in solution. The microspheres could be loaded with different doses ranging from to 142-335 mg per ml of hydrated microspheres. Elution experiments were carried out

20 on these microspheres (table 1). Microspheres were washed to determine quick burst in various media as in table 1. Then samples were placed in 10 ml solvent and absorbance read after 10mins, a further 20 ml added and absorbance read after 10 mins, this was repeated up to 90 mls and elution was monitored up to 24hrs (table 1). Elution rate ranged between 20% -

25 43% with an average of 25% in most experiments and approximately 15% was quick burst.

Loading solution ml	Loading mg/ml Bead	Eluted Drug (mg)	Quick Burst/Wash out Solvent	Elution Solvent Used
2	187.08	47	100% ethanol	50%ethanol
2	207.7	53	50% ethanol	50%ethanol
2	235.53	60	100% ethanol	0.9% Saline (pH12)
2	177.3	47	0.9% Saline (pH12)	0.9% Saline (pH12)
2	185.24	83	0.9% Saline (pH12)	0.9% Saline (pH12)
2	142.82	57	0.9% Saline (pH12)	0.9% Saline (pH12)
3	323.7	77	0.9% Saline (pH12)	0.9% Saline (pH12)

Table 1: Elution experiments of Ibuprofen Free Acid

Example 7: Loading of Release of Ibuprofen Sodium Salt from Microspheres

Two samples of 1 ml of hydrated Low AMPS beads (700-1100 μm, example 1) were used. For preparation of the loading solutions: a) 1 g of ibuprofen sodium salt (SIGMA) was dissolved in 4 ml of water (ROMIL) and b) 1 g of Ibuprofen sodium salt (SIGMA) was dissolved in 4 ml of ethanol (ROMIL) to give a final concentration of 250 mg/ml. Once prepared, the absorbances of the solutions were read by UV at 263 nm and dilutions were made to produce a standard curve. 2ml of the Ibuprofen solution was added to a vial containing 1 ml of beads and timing was started. The vials were placed on a roller mixer at room temperature for the entire experiment. At predetermined time points (0, 10, 20, 30 and 60 min) 100 μl was removed, diluted as necessary (1/200) and read at 263 nm. From the readings and the standard curve, the concentration of the solution at each time point was calculated. The amount of drug loaded onto the beads was measured by the depletion of the drug in solution when extracted with the beads. From the data the mg drug loaded per 1 ml of hydrated beads were calculated and the graph plotted. From the data shown in figure 10 it can be seen that when

31

the ibuprofen is loaded from ethanol a maximum loading is reached in about 20 minutes before loading levels again begin to decrease. This is a consequence of a competition between drug/solvent penetration into the microspheres and a concomitant de-swelling of the beads as the ethanol

5   dehydrates them. After 20 minutes the de-swelling becomes predominant and some of the drug solution is forced from the interstices of the bead as its structure collapses.

    For elution studies, 1 ml of the 250 mg/ml loaded beads was transferred into a glass-brown container filled with 100 ml of PBS and timing

10   was started. The containers were placed in the roller mixer at room temperature for the entire experiment. At predetermined times (15, 30, 60 and 120 minutes) 1 ml of the solution was removed, read and then placed back into the container, so the volume remained constant for the entire experiment. Samples were read at 263 nm and concentrations were

15   calculated from the equation of the ibuprofen standard curve. From the data, the mg of drug eluted per 1 ml of hydrated beads was calculated and the graph plotted (Figure 11).

        Example 8: Loading and Elution of Ibuprofen Free Acid from
                          Microspheres

20   Five samples of 1 ml of hydrated beads Low A<PS 700 to 1100 µm were used. For each sample, 1 ml of beads in phosphate buffered saline (PBS), measured with a 10ml- glass cylinder, was transferred to a glass container and all the PBS was carefully removed with a glass Pasteur pipette. For preparing the loading solutions: 2 g of Ibuprofen free acid

25   (SIGMA) was dissolved in 8 ml of ethanol (ROMIL) to give a final concentration of 250 mg/ml. Once prepared, the absorbances of the solution and dilutions were read by UV at 263 nm to produce a standard curve. 2ml of the ibuprofen solution was added to a vial containing 1 ml of beads (previously prepared, details above) and timing was started. This was done

30   in duplicate; in the second experiment 1ml of ibuprofen solution was added to 1ml of ethanol (so the final concentration of the solution was 125 mg/ml).

32

As controls 2ml of ethanol was added to one vial and 2 ml of PBS was added to another vial, each vial containing 1ml of beads. The vials were placed on the roller mixer at room temperature for the entire experiment. At predetermined time points (0, 20, 40, 60 and 120 min) 100 µl was removed,

5   diluted as necessary (1/200) and read at 263 nm. From the readings and the standard curve, the concentration of the solution at each time point was calculated. The amount of drug loaded onto the beads was measured by the depletion of the drug in solution. From the data the mg drug loaded per 1 ml of beads were calculated and the graph plotted (figure 12). Again, as in

10   example 7, the contraction of the beads when exposed to ethanol causes an optimum loading to be obtained at around 20 mins before contraction causes expulsion of the drug solution from the beads.

        Loaded beads from the experiment above were used for elution experiments. 1 ml of the 250 mg/ml loaded beads was transferred into a

15   glass-brown container filled with 20 ml of PBS and timing was started. The containers were placed in the roller mixer at room temperature for the entire experiment. At time 10 minutes, 30 ml of fresh PBS was added into the container and at time 2 h another 50 ml of PBS was added into the container to give a final volume of 100 ml. At predetermined time points (0, 5, 10, 20,

20   30, 45, 60, 90 min and 2, 3 and 24 hours) 1 ml of the solution was removed, read and then placed back into the container. Samples were read at 263 nm and concentrations were calculated from the equation of the ibuprofen standard curve. From the data, the mg of drug eluted per 1 ml of hydrated beads was calculated and the graph plotted (figure 13). Controls from the

25   experiment above were eluted in the same conditions.

Example 9: Loading and Elution of Ibuprofen into Microspheres using pH and Solvent Triggers

        Six samples of 1 ml of beads (700-1100 µm) were used. For each sample, 1 ml of beads in phosphate buffered saline (PBS), measured with a

30   10ml glass cylinder, was transferred to a glass container and all the PBS was carefully removed with a glass Pasteur pipette. For preparing the

loading solutions: a) 4 g of ibuprofen sodium salt (SIGMA) were dissolved in 16 ml of water (ROMIL) to give a final concentration of 250 mg/ml and b) 1 g of ibuprofen free acid (SIGMA) was dissolved in 4 ml of ethanol (ROMIL) to give a final concentration of 250 mg/ml. Once prepared, the absorbances of

5   the solution and dilutions of the aqueous and of the alcoholic solutions were read by UV at 263 nm to produce standard curves. The aqueous loading solution of ibuprofen sodium salt was then used to load 3 samples (A, B and C) of beads. Sample A was loaded by adding 2ml of the ibuprofen salt solution to a vial containing 1 ml of hydrated beads for 20 minutes

10 (previously prepared, details above). The vial was placed on the roller mixer at room temperature for the entire experiment. Once loaded, the remaining solution was removed, measured in a graduated measurement cylinder and read at 263 nm. From the readings and the standard curve, the concentration of the solution was calculated. The amount of drug loaded

15 onto the beads was calculated by the subtracting the amount of drug in solution from the amount in the starting loading solution. From the data the mg drug loaded per 1 ml of beads for sample A was 101mg/ml. As a control 2ml water with no drug was "loaded" into beads.

For sample B, the loading was the same as for sample A, but, instead

20 of the residual liquid being immediates removed, 2 ml of water at pH 1 (obtained by adding HCl to the water) was added to the vial. This was kept in the roller mixer for 20 minutes. After that, the solution was removed, and the concentration of ibuprofen remaining was determined and thus the amount loaded into the beads. The loading for sample B was found to be

25 129.5mg/ml loading. As control 2 ml of water at pH 1 was added to a vial containing 1 ml of beads.

For sample C 2 ml of ethanol for 20 min; after that, the solution was removed and the concentration or ibuprofen free acid remaining was determined thereby allowign calculation of the amount loaded into the bead.

30 The amount loaded was found to be 47mg/ml bead. As control, for sample C, 2 ml of ethanol was added to a vial containing 1 ml of beads.

34

In sample D, 2 ml of the ethanol solution containing 250 mg/ml of ibuprofen free acid was added and kept in the roller mixer for 20 minutes. After that, the solution was removed and the concentration of ibuprofen determined. The loading of ibuprofen free acid in to the bead was found to

5　be 110.8mg/ml.

Elution was carried out with 1 ml of the loaded beads transferred into a glass-brown container filled with 100 ml of PBS and timing was started. The containers were placed in the roller mixer at room temperature for the entire experiment. At predetermined times (15, 30, 60 and 3 and 5 hours) 1

10　ml of the solution was removed, read and then placed back into the container, so the volume remained constant for the entire experiment. Samples were read at 263 nm and concentrations were calculated from the equation of the ibuprofen standard curve. From the data, the amount of drug eluted per 1 ml of hydrated beads was calculated and the graph plotted

15　(figure 14). Controls from the experiment above were eluted in the same conditions. Controls are not presented in the graphs because the concentrations eluted remained below detection limits from the entire experiment.

It can be seen that where the pH has been adjusted, release of the

20　ibuprofen is slowed significantly. This is due to the generation of the ibuprofen free acid in-situ within the beads and hence the solubility of the drug is drastically decreased. Similarly, if the beads are exposed to ethanol. after loading, the structure is collapsed due to water expulsion (as in Example 7). Upon rehydration in the buffer, the release profile of the free

25　acid is slowed even more, suggesting that the collapsing process helps to impede drug dissolution from the polymer matrix.

Example 10: Loading and Release of Ketoprofen from
Microspheres

A ketoprofen solution of 30mg/ml in ethanol was prepared (Sigma

30　Aldrich). 0.5ml of 500-710μm low AMPS or high AMPS type microspheres (example 1) was added to 5ml of ketoprofen solution in duplicate (a & b),

35

and uptake was monitored by UV over 72 hours. After an initially higher
uptake which was not maintained, maximum loading occurred at 24 hours
with the low AMPS microspheres showing approximately 12mg ketoprofen
loaded /ml spheres and the high AMPS microspheres showing approximately
5   10 mg ketoprofen loaded /ml spheres.

Release of ketoprofen from the spheres loaded for 24 hours was
determined as follows: the excess loading solution was removed by glass
Pasteur pipette from the loaded microspheres described above. Each
sample of loaded microspheres was placed in a glass jar containing 100ml
10   water and the jars were placed in a shaking water bath at 37°C. Release
was measured by UV over 24 hours, at which point a further 100ml water
was added to each jar. UV measurement was continued for 6 hours after
this. Approximately 20-25% of the loaded drug was released from the
microspheres, this being equivalent to approximately 2.5mg/ml of
15   microspheres. (% calculated from the maximum loading obtained after 24
hours). This was released in the first 15 minutes of the elution. The addition
of extra water after 24 hours did not bring about any further release of the
drug (figure 15). There appeared to be little effect on release rate between
the low and high AMPS in the microsphere formulation.

20   **Example 11: Loading and Release of Naproxen from**
Microspheres

A naproxen solution of 30mg/ml in ethanol was prepared from
naproxen obtained from Sigma Aldrich. 0.5ml of 500-710µm low AMPS or
high AMPS microspheres was added to 5ml of naproxen solution in
25   duplicate, and uptake was monitored by UV over 168 hours (7 days). The
microspheres took up approximately 35-40mg naproxen /ml of spheres over
168 hours. Initial rapid uptake was followed by apparent partial release,
then more gradual uptake (figure 16).

The excess loading solution was removed by glass Pasteur pipette
30   from the loaded microspheres described in Example 8. Each sample of
loaded microspheres was placed in a glass vial containing 10ml water and

the vials were placed in a shaking water bath at 37°C. Release was
measured by UV over 17 hours, at which point the microspheres were
placed in 10ml fresh water. UV measurement were continued for 7 hours
after this. Approximately 17-25% of the loaded drug was released from the
5   microspheres, this being equivalent to approximately 6-9mg/ml of
microspheres. This was released in the first 5 minutes of the elution (figure
17). The transfer of the microspheres to fresh water after 17 hours did not
bring about any further release of the drug.

Example 12: Loading and Release of Salicylic acid from
10   **Microspheres**

A salicylic acid solution of 5mg/ml in ethanol was prepared from
salicylic acid obtained from Sigma Aldrich. 0.5ml of 500-710µm low AMPS
or high AMPS microspheres were added to 5ml of salicylic acid solution in
duplicate, and uptake was monitored by UV over 24 hours. The
15   microspheres took up a maximum of approximately 3-4mg salicylic acid /ml
of microspheres after 3-4 hours, but this had decreased to 2-3 mg/ml of
microspheres after 24 hours.

The elution of the drug was assessed as follows: the excess loading
solution was removed by glass Pasteur pipette from the loaded
20   microspheres. Each sample of loaded microspheres was placed in a glass
jar containing 100ml water and the vials were placed in a shaking water bath
at 37°C. Release was measured by UV over 60 hours, at which point the
microspheres were placed in 10ml fresh water. UV measurement were
continued for 60 hours after this. The low AMPS microspheres released
25   approximately 25% of the salicylic acid loaded, whereas the high AMPS
microspheres released approximately 30% of the salicylic acid loaded. For
both microsphere types the majority of the drug was released within the first
15 minutes (figure 18). The transferral of the spheres into fresh water did
not bring about any further release of the drug.

CLAIMS

1.   Use of water-insoluble polymer and, associated with polymer in a releasable form, a pharmaceutically active agent which is a non-steroidal anti-inflammatory agent, in the manufacture of a composition for use in a method of uterine fibroid embolisation, in which the pharmaceutical active is released from the polymer at the site of embolisation.

2.   Use according to claim 1, in which the polymer is in the form of particles.

3.   Use according to claim 2 in which the particles are substantially spherical in shape.

4.   Use according to claim 2 or 3 in which the particles have particle sizes when equilibrated in water at 37°C in the range 40 to 1500 µm, preferably 100 to 1200 µm.

5.   Use according to any preceding claim in which the particles are water-swellable.

6.   Use of water-insoluble polymer and, associated with polymer in a releasable form, a pharmaceutically active agent in which is a cyclooxygenase (COX) inhibitor in the manufacture of a composition for use in a method of uterine fibroid embolisation, in which the pharmaceutical active is released from the polymer at the site of embolisation.

7.   Use according to claim 6, in which the COX inhibitor is selective for COX-1.

8.   Use according to claim 6 in which the COX inhibitor is selective for COX-2.

9.   Use according to any preceding claim in which the pharmaceutically active agent is selected from celecoxib, rofecoxib, diclofenac, diflunisal, etodolac, flurbiprofen, ibuprofen, indomethacin, ketoprofen, ketorolac, nabumetone, naproxen, oxaprozin, piroxicam, sulindac, tolmetin and pharmaceutically acceptable salts thereof.

10.   Use according to any preceding claim in which the pharmaceutically active agent is selected from ibuprofen, flurbiprofen,

diclofenac, ketorolac, naproxen, ketoprofen and salicyclic acid and
pharmaceutically acceptable salts thereof.

11.   Use according to any preceding claim in which the polymer is
synthetic and biostable.

12.   Use according to any preceding claim in which the polymer is
cross-linked.

13.   Use according to claim 11 in which the polymer is covalently
cross-linked.

14.   Use according to any preceding claim in which the polymer is
formed by the radical polymerisation of poly(vinyl alcohol) macromer having
pendant ethylenically unsaturated groups.

15.   Use according to claim 14 in which the pendant groups are
(alk) acrylic groups.

16.   Use according to claim 14 or 15 in which the macromer is
copolymerised with ethylenically unsaturated comonomer.

17.   Use according to claim 16 in which the comonomer is ionic
comonomer.

18.   Use according to claim 16 or claim 17 in which the comonomer
is an acrylic compound.

19.   A pharmaceutical composition comprising microspheres of
water-insoluble, water-swellable polymer formed by the radical
polymerisation of poly(vinyl alcohol) macromer having pendant ethylenically
unsaturated groups and, associated with the polymer in releasable form, a
pharmaceutically active agent which is a non-steroidal anti inflammatory
agent.

20.   A pharmaceutical composition comprising microspheres of
water-insoluble, water-swellable polymer formed by the radical
polymerisation of poly(vinyl alcohol) macromer having pendant ethylenically
unsaturated groups and, associated with the polymer in releasable form, a
pharmaceutically active agent which is a cyclooxygenase inhibitor.

41

21.   A composition according to claim 20 in which the active agent is selective for COX-1.

22.   A composition according to claim 20 in which the active agent is selective for COX-2.

23.   A composition according to claim 19 or 20 in which the active agent is selected from celecoxib, rofecoxib, diclofenac, diflunisal, etodolac, flurbiprofen, ibuprofen, indomethacin, ketoprofen, ketorolac, nabumetone, naproxen, oxaprozin, piroxicam, sulindac, tolmetin and salts thereof.

24.   A composition according to claim 19 or 20 in which the pharmaceutically active agent is selected from ibuprofen, flurbiprofen, diclofenac, ketorolac, naproxen, ketoprofen and salicyclic acid and pharmaceutically acceptable salts thereof.

25.   A composition according to any of claims 19 to 24 in which the macromer is formed by the reaction of poly(vinyl alcohol) with N-acryloylaminoacetaldehyde.

26.   A composition according to any of claims 19 to 25 in which the macromer is copolymerised with ethylenically unsaturated comonomer.

27.   A composition according to claim 26 in which the comonomer is ionic.

28.   A composition according to claim 25 and claim 27 in which the comonomer is an acrylic compound.

29.   A method of loading a non-steroidal anti-inflammatory agent which has an acid group into a water-insoluble, water swellable polymer vehicle including the steps of

a)   contacting water-swellable cross-linked poly(vinyl alcohol) polymer with an aqueous solution of the agent at a pH at above the pKa of the acid group,

b)   adding acid to the product of step a) so as to reduce the pH of the aqueous liquid in contact with polymer to below the pKa of the acid group; and

c)   recovering the polymer with loaded agent in free acid form.

42

30.   A method according to claim 29 in which the active agent is a cyclooxygenase inhibitor.

31.   A method according to claim 30 in which the active agent is selective for COX-1.

32.   A method according to claim 30 in which the active agent is selective for COX-2.

33.   A method according to any of claims 29 to 32 in which the agent is selected from napoxen, sulindac, diclofenac, indomethacin, ibuprofen, acetyl salicylate, ketorolac, ketoprofen, flurbiprofen and suprofen, preferably ibuprofen.

34.   A method according to any of claims 29 to 33 in which the pH of the aqueous solution in step a) is at least 5, and the pH of the liquid after step b) is less than 3.

35.   A method according to any of claims 29 to 34 in which the polymer is in the form of particles which are suspended in the aqueous solution in step a).

36.   A method according to claim 35 in which the particles are substantially spherical.

37.   A method according to claim 35 or 36 in which the particles have particle sizes when equilibrated in water at 37°C in the range 40 to 1500 µm, preferably 100 to 1200 µm.

38.   A method according to any of claims 29 to 37 in which the poly(vinyl alcohol) is cross-linked by aldehyde.

39.   A method according to any of claims 29 to 37 in which the polymer is formed by the radical polymerisation of poly(vinyl alcohol) macromer having pendant ethylenically unsaturated groups and, associated with the polymer in releasable form, a pharmaceutically active agent which is a non-steroidal anti inflammatory agent.

40.   A method according to claim 39 in which the macromer is formed by the reaction of poly(vinyl alcohol) with N-acryloylaminoacetaldehyde.

41.   A method according to claim 39 or 40 in which the macromer is copolymerised with ethylenically unsaturated comonomer.

42.   A method according to claim 41 in which the comonomer is ionic.

5   43.   A method according to claim 41 or 42 in which the comonomer is an acrylic compound.
